EFFECT OF THE WORLD:

It feels somehow safe to say that the state of the world , in particular with the countries surrounding England and other parts of the world have been degrading due this virus in the last 2 years roughly. The results of the countries are shown with percentage of infected with light blue colour and this percentage of growths, into light yellow colour with a small percentage increase orange colour for medium increased percentage and red colour for very high increase.

There was an article plus the media said there was a decrease on the global pandemic . The graph shows the rising of the basic measurements of April since that time it has elevated and its kept on steady level. But steady for how long thats the main question everyone is asking and myself included , the economy of the world has decreased so much and many people are getting redundant due to this.

Below I will explain few of the Cases of Covid19

Been stable...

During all the lockdown measures carried out in countries like China South Korea and USA for now there will be less danger but in the case it flares up the virus still continues to grow. The lockdown measures involves school closed , work at home if possible pub and clubs closed . The hospitality industry and the travel industry are facing more disadvantages of bringing up the economy , for example the UK tends to have all these above factors with a ban the steepest infection curve . The Uk and Singapore has become two countries which have a new case of coronavirus the mutant virus which is contagious and awaiting on the vaccines and cases start rising daily.

The downfall of the virus

The pointy curves exhibited by New Zealand and Austria give us an indication of where containment measures were successful at curbing the spread of the virus. This type of pronounced curve is less common, and is generally seen in nations with smaller populations. Italy which experienced one of the most severe outbreaks, is finally emerging from the world's longest nationwide lockdown. Switzerland and the Netherlands both had some of the highest confirmed case rates per capita, but are now in better situations as fresh cases drop off.

The background of the slide features several stylized, blue, spherical virus particles with protruding spikes, resembling coronaviruses. These particles are scattered across the left half of the slide, with some in sharp focus and others blurred in the background.

The uprising and growth of the Virus ...

The virus is spreadout in continents like Asia Europe South America and Russia this caused outbreak between the borders of these continents . Russia did close its borders last than everyone else so the infection was the steepest due to this the number of cases are rises till now and the last week. This is has brought up concern because of his large population and till the vaccines arrive they got few resources to deal with with COVID 19.

Conclusion:

The above 3 points explain the 3 factors of coronavirus around the world , its recorded that for to date there are 86 million cases of covid19 around the world , with a total loss of 2 million people

and the recovered so far are unknown because daily the case rise.
